## Contract Description

The purpose of this work is to develop techniques to overcome the fundamental limits of present methods for high resolution spectroscopy and frequency standards--the second order and residual first-order Doppler shifts. To this end, we study suitable frequency reference transitions in ions which are stored in electromagnetic traps and cooled by radiation pressure to  $< 1\text{K}$ .

## Scientific Problem

The scientific problems are (1) to find ways to suppress second order and residual first order Doppler shifts in atomic spectroscopy in a fundamental way--by substantially reducing the kinetic energy of ions stored in electromagnetic traps, (2) to study suitable reference transitions in ions that can be used as frequency standards, and (3) to study the problems (i.e., systematic effects) generic to all stored ion frequency standards. The goal is to achieve at least a factor of 100 improvement in accuracy over the present best device, the Cesium beam frequency standard, which has an accuracy of approximately 2 parts in  $10^{14}$ .

## Scientific and Technical Approach

Laser cooling is employed on all experiments in order to suppress Doppler shifts. Temperatures as low as  $40\text{ }\mu\text{K}$  have been achieved and temperatures less than  $0.1\text{K}$  are routinely achieved. To avoid light shifts on "clock" transitions we investigate "sympathetic cooling" where one ion species is laser cooled and by Coulomb collisions cools another ion species of spectroscopic interest. We continue experiments on  $\text{Mg}^+$  and  $\text{Be}^+$  in order to study generic problems with traps since these ions are easier to laser cool. We are conducting separate experiments for  $\text{Hg}^+$  ions. These experiments have the goal of realizing a frequency standard with  $10^{-15}$  or better accuracy.

### I. Summary of progress since Oct. '90.

1.  $^9\text{Be}^+$  hyperfine pressure shift. We have conducted experiments to identify the cause of the large pressure shift we discovered previously. We have measured the pressure shift of the  $^9\text{Be}^+$  hyperfine clock transition due to various gasses which are known to be in the kind of vacuum system we use.  $\text{CH}_4$  gave a large anomalous shift,  $\text{H}_2$ ,  $\text{N}_2$ ,  $\text{O}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{He}$ , and  $\text{Ar}$  gave no anomalous shift.
2. Linear Paul Trap and High Resolution Microwave Spectroscopy of  $\text{Hg}^+$  : "Strings" and more complicated crystalline structures of laser-cooled ions have been observed in an rf trap with linear geometry. This trap should give, for many stored ions, the same small Doppler shifts as achieved for single ions in a Paul trap of more conventional quadrupole geometry. Signal-to-noise ratio will be increased due to the larger numbers of ions. The  $^{199}\text{Hg}^+$  40.5 GHz microwave resonance has been detected using microwave/laser double resonance detection. Linewidths of about 0.2 Hz have been observed.
3. Penning Trap Density Limitations: We have identified a mechanism which limits the density for ions in a Penning trap. This limit is caused by a static-field-axial-asymmetry-induced plasma heating resonance which

depends on density and trapping parameters. This will have implications for the large scale storage of particles in Penning traps such as the storage of antiprotons. A physical review letter has been recently published and further measurements and theoretical analysis are underway.

4. Search for anomalous spin-dependent forces using  $^9\text{Be}^+$  hyperfine spectroscopy: By examining the "clock" transition in  $^9\text{Be}^+$ , we have been able to place upper limits on the strength of anomalous dipole-monopole and dipole-dipole couplings for the electron and neutron.
5. Theory of Sisyphus cooling for a bound atom (ion): Sisyphus cooling for a trapped ion has been theoretically investigated (D. J. Wineland, with J. Dalibard and C. Cohen-Tannoudji) and submitted for publication.
6. Observation of "Atomic Projection" noise: We have observed, in a clear way, the noise in spectroscopic measurements due to fluctuations in the number of atoms (ions) which make the transition when resonance radiation is applied. This fundamental source of noise is in addition to other sources of noise observed previously.
7. Measurement of  $g_J(\text{Mg}^+)$ : The electronic g-factor of  $^{26}\text{Mg}^+$  has been measured relative to  $^9\text{Be}^+$  to a precision of about  $10^{-8}$ . With our past measurement of the  $^9\text{Be}^+$  g-factor, we can determine the magnesium g-factor to a precision of 1.6 parts in  $10^7$ . Comparison with theory is made.
8. Synchrotron Frequency Divider: High order nonlinear excitation of the motion of a single electron has been studied. Studying the excitation of the magnetron motion has proven fruitful because of the relative insensitivity to magnetic field fluctuations.
9. Observation of time varying radiation pressure forces: The effects of time varying dipole forces and radiation pressure forces on trapped ions were studied theoretically and experimentally.
10.  $\text{Hg}^+$  optical frequency standard: Efforts to stabilize the 282 nm laser for the quadrupole transition in  $^{199}\text{Hg}^+$  have resulted in linewidths less than 25 Hz. Efforts to apply this radiation to the ion have been hampered because of the limited lifetime ( $\approx 1$  hr) of  $\text{Hg}^+$  ions in the trap (due to dimer formation). Recent effort has been shifted to developing an apparatus with cryogenic pumping which should eliminate ion loss problems and also prevent possible pressure shift problems encountered in the  $^9\text{Be}^+$  experiments.
11. Laser Cooled Refrigerator and Detector: A coupled trap is under construction. This first experiment is designed to "sympathetically" cool electrons which are stored in one trap by electronically coupling them to laser-cooled ions which are contained in another trap.
